

Stopping a multi-light capture when the reconstruction stops changing

Synthetic incised inscription under a 48-LED dome. The planner picks the next light and decides when to stop without ever seeing where the strokes are; legibility is scored afterwards against the known mask.

Legibility saturates long before the dome is finished

Read this the unflattering way. Most of the saving is the stopping rule, not the choosing: stopping takes the dose to about a quarter, choosing takes it to about a sixth. The object, the dome and the dose figures are all synthetic. No real object has been imaged, and the light budget is invented— that is the part a conservator has to supply. Across six synthetic stacks at three noise levels the adaptive arm used fewer captures in 6 of 6.
